## Lab: Standing Waves on a String

## I. DATA COLLECTION

- Hang diferent masses from the standing wave apparatus as demonstrated in class. When the mass is just right you should see a nodal pattern. Construct the following table

| \# of nodes | $\lambda(\mathrm{m})$ | Mass $(\mathrm{kg})$ |
| :---: | :--- | :--- |
| 4 |  |  |
| 5 |  |  |
| etc |  |  |

## II. ANALYSIS

1. Using $v=\lambda f$ and the fact that the tension is $T=M g$, with $f=120 \mathrm{~Hz}$ and $g=9.8 \mathrm{~m} / \mathrm{s}^{2}$, construct the following table

| \# of nodes | $v^{2}(\mathrm{~m} / \mathrm{s})$ | $T(\mathrm{~N})$ |
| :---: | :---: | :---: |
| 4 |  |  |
| 5 |  |  |
| etc |  |  |

2. Using the equation

$$
v=\sqrt{\frac{T}{\mu}}
$$

argue that if tension is on the $y$ axis and $v^{2}$ is on the $x$ axis the slope of this line should be the mass density $\mu$.
3. Make a graph of $T$ vs. $v^{2}$ using the plotting package. Perform a fit of this line to determine the slope - the intercept should be constrained to zero. The slope is a measurement of the mass density.
4. Measure the mass density $\mu$ directly by measuring the mass and length of a similar string:

$$
M_{\text {string }}=\quad L_{\text {string }}=
$$

5. Determine the percent difference between part 3 and part 4 .
