Particle spectra and correlations in a thermal model

Wojciech Broniowski
H. Niewodniczański Institute of Nuclear Physics, Cracow, Poland

Collective flow and QGP properties, RIKEN/BNL, 17 November 2003

WB+ WF+ Brigitte Hiller (Coimbra), PRC 68 (2003) 034911
Piotr Bozek+ WB+WF, nucl-th/0310062
Outline

1. Single-freeze-out approximation
2. Importance of hadronic resonances
3. Yields
4. $p_t$-spectra
5. $\pi^+\pi^-$ invariant-mass correlations
6. Balance functions
7. HBT radii
8. Elliptic flow
Thermal models

Koppe (1948), Fermi (1950), Landau, Hagedorn, Rafelski ..., Heinz ..., Gaździcki, Braun-Munzinger ..., Magestro, Csörgő ..., Becattini ..., Hirano, ...

\( \sim e^{-(E - \mu)/T} \)
Specific features of our approach

1. **Single freezeout approximation**: $T_{\text{chem}} = T_{\text{kin}} = T$, single freeze-out. A radical simplification, supported by the RHIC HBT results: $R_{\text{out}}/R_{\text{side}} \sim 1$, $R_{\text{side}}(\phi)$ has out-of-plane elongation, resonances seen abundantly $\rightarrow$ short time between the freeze-outs (explosive scenario).

$T$ and $\mu_B$ are fitted from ratios of $dN/dy$ at midrapidity

2. **Ockham rasor**: No $\gamma$-factors for strangeness (Rafelski), excluded-volume effects (Gorenstein), canonical (Redlich) or microcanonical ensemble (Becattini)
3. **Hagedorn**: Complete treatment of resonances (important due to the Hagedorn-like exponential growth of the number of states)

75% of pions and protons come from decays of higher states, 80% of Λ’s, 60% of Ξ’s, 30% of Ψ’s, . . . !

(from WB+WF, PLB 490 (2000) 223)
4. **Geometry and flow:** We take the hypersurface (inspired by Bjorken and Buda-Lund models) of the form

\[
\tau = \sqrt{t^2 - r_z^2 - r_x^2 - r_y^2} = \text{const}
\]

and constrain the transverse size, \( \rho = \sqrt{r_x^2 + r_y^2} < \rho_{\text{max}} \). The geometric parameters \( \tau \) and \( \rho_{\text{max}} \), of the order of a few fm, are fitted to the \( p_\perp \)-spectra (\( \tau^3 \) is the overall normalization constant, \( \rho_{\text{max}} \) controls the slopes). The hydrodynamic four-velocity is (Hubble law)

\[
u^\mu = \partial^\mu \tau = \frac{x^\mu}{\tau} = \frac{t}{\tau} \left( 1, \frac{r_z}{t}, \frac{r_x}{t}, \frac{r_y}{t} \right)
\]

**Boost invariance** is a good approximation for midrapidity

Other choices can be tested (Heinz+Sollfrank+Wiedemann, Torrieri+Rafelski) (e.g. blast wave)

Altogether 4 parameters
Ratios

For a boost-invariant model \( \frac{dN_i/dy}{dN_j/dy} = \frac{N_i}{N_j} \) and ratios do not depend on geometry/flow.

\[
\begin{array}{|c|c|c|}
\hline

\hline
\end{array}\]
Resonance decays in $p_{\perp}$-spectra

The integration over $x_{N-1} \ldots x_2$ is unconstrained, while the integration over $x_N$ is constrained to the hypersurface $\Sigma$.

$$E_{p_1} \frac{dN_1}{d^3p_1} = \int \frac{d^3p_2}{E_{p_2}} B(p_2, p_1) \ldots \int \frac{d^3p_N}{E_{p_N}} B(p_N, p_{N-1}) \int d\Sigma_{\mu} (x_N) \ p_N^\mu f_N [p_N \cdot u (x_N)]$$

$$B(p_i, p_{i-1}) = \frac{b}{4\pi p_{i-1}^*} \delta \left( \frac{p_i \cdot p_{i-1}}{m_i} - E_{i-1}^* \right)$$

Results for the transverse-momentum spectra

Min. bias $p_\perp$-spectra of pions, kaons, protons and antiprotons as evaluated from our model with $\tau = 6$ fm, $\rho_{\text{max}}/\tau = 0.76$, compared to the earliest PHENIX data (Velkovska, nucl-ex/0105012). Very good agreement up to $p_\perp \sim 2$ GeV. At larger values, where hard processes enter, the model falls below the data.
“Cooling” via decays

Resonance decays lower the inverse slope by about 30 MeV
STAR + PHENIX @ 130 GeV
most central

\[ \frac{dN}{2\pi p_T dp_T dy} |_{y=0} \quad [\text{GeV}^{-2}] \]

\( K^- \), \( \pi^- \)
\( p \)
\( \phi \)
\( (K^{*0}+\bar{K}^{*0})/2 \times 0.1 \)

\( p_\perp [\text{GeV}] \)

\[ T = 165 \text{ MeV} \]

\( \phi \) – very weak interactions, serves as a thermometer

\( K^* \) – resonance, lower \( T \) would lead to much less \( K^* \)’s

(Experimental \( \Xi \)’s went down by \( \sim \) a factor of 2)

No special treatment of \( \Omega \)’s
Two different expansion models

\[ \frac{d^2N}{2\pi p_T dp_T} \, [\text{GeV}^{-2}] \]

(a) PHENIX, min. bias
(b) PHENIX, min. bias
(c) STAR + PHENIX, most central

thick: present model, thin: blast-wave (from WB+WF, PRL 87 (2001) 272302)
(data at different centrality, or impact parameter)

Centrality $c$ is defined as a percentage of the most central events. To a very good accuracy

$$c \simeq \frac{\pi b^2}{\sigma_{\text{tot}}^{\text{inel}}} \simeq \frac{b^2}{4R^2}$$

Wounded-nucleon scaling

The number of wounded nucleons, \( w(b) \) (solid line) and the approximating function \( w(0)(1 - c(b))^3 \) (dashed line), are plotted as functions of the impact parameter \( b \).

Since the multiplicity of hadrons produced in our model is proportional to \((1 - c)^3\) at low and moderate values of \( c \), the model conforms to the wounded-nucleon scaling
How was it at SPS?

(Brown+Shuryak, Kolb-Prakash, Rapp, Pratt+Bauer)
The phase-shift formula for the density of resonances

Resonances provide kinematic correlations

Beth, Uhlenbeck (1937); Dashen, Ma, Bernstein, Rajaraman (1974); Weinhold (1998), Friman, Nörenberg; WB, WF, B. Hiller, PRC 68 (2003) 034911; Pratt, Bauer, nucl-th/0308087

\[
\frac{dn}{dM} = f \int \frac{d^3p}{(2\pi)^3} \frac{d\delta_{\pi\pi}(M)}{\pi dM} \frac{1}{\exp \left( \frac{\sqrt{M^2+p^2}}{T} \right) \pm 1}
\]

For narrow resonances \(d\delta(M)/dM \simeq \pi \delta(M - m_R)\), and

\[
n_{\text{narrow}} = f \int \frac{d^3p}{(2\pi)^3} \frac{1}{\exp \left( \frac{\sqrt{m_R^2+p^2}}{T} \right) \pm 1}
\]

In a thermal system the density of states changes \(\rightarrow\) phase shifts appear (not the spectral function) [S. Pratt, Warsaw Meeting on Particle Correlations, 2003]
Small contribution from $\sigma$, negative and tiny contribution from $I = 2$, $\rho$-peak slightly shifted to lower $M$, $1/\sqrt{M - 4m_{\pi}^2}$ behavior for the $\sigma$
Warm-up calculation - static source

We compute the spectra at mid-rapidity, hence

\[
\left. \frac{dn}{dMdy} \right|_{y=0} = \sum_i f_i \int_{0.2\text{GeV}}^{2.2\text{GeV}} \frac{p \, dp}{(2\pi)^2} \frac{d\delta_i(M)}{dM} \exp \left( \frac{\sqrt{M^2 + p^2}}{T} \right) - 1
\]

steep

W. Broniowski, BNL’03
Cuts/flow + feeding from resonances

Flow has no effect on the invariant mass of a pair of particles produced in a resonance decay, since the quantity is Lorentz-invariant. Nevertheless, it affects the results since the kinematic cuts in an obvious manner break this invariance.

HBT radii

\[ S(x, p) = \int d\Sigma \mu_p \delta(x' - x) f(x', p) \]

\[ C(\vec{q}, \vec{P}) = 1 + \frac{\left| \int d\Sigma(x) \cdot u(x) e^{i\vec{q} \cdot \vec{x}} S(\vec{P} \cdot u(x)) \right|^2}{\int d\Sigma \cdot u S((\vec{P} + \frac{\vec{q}}{2}) \cdot u(x)) \int d\Sigma \cdot u S((\vec{P} - \frac{\vec{q}}{2}) \cdot u(x))} \]

The pionic HBT radii for most-central collisions @130 GeV, and their ratio, as predicted by the model + excluded volume corrections (\sim 30% enhancement of model radii) and measured by PHENIX
Excluded-volume (Van der Waals) corrections

Such effects were found important in previous studies of the particle multiplicities in ultra-relativistic heavy-ion collisions, leading to a significant dilution of system. They bring in a factor (Gorenstein)

\[
e^{-Pv_i/T} \frac{1}{1 + \sum_j v_j e^{-Pv_j/T n_j}},
\]

into phase-space integrals, where \( P \) denotes the pressure, \( v_i = 4 \frac{4}{3} \pi r_i^3 \) is the excluded volume, and \( n_i \) is the density of particles of species \( i \). The pressure is calculated self-consistently from the equation

\[
P = \sum_i P^0_i (T, \mu_i - Pv_i/T) = \sum_i P^0_i (T, \mu_i) e^{-Pv_i/T}
\]

where \( P^0_i \) is the partial pressure of the ideal gas of hadrons of species \( i \). If \( r_i = r \), \( v_i = v \), the excluded-volume correction produces a common scale factor, \( S^{-3} \). Then

\[
\frac{dN_i}{d^2p_\perp dy} = \tau^3 \int_{-\infty}^{+\infty} d\alpha \int_{0}^{\rho_{\text{max}}/\tau} \sinh \alpha \cdot d(\sinh \alpha \perp) \int_{0}^{2\pi} d\xi \cdot p \cdot u \cdot S^{-3} f_i (p \cdot u)
\]

The presence of the factor \( S^{-3} \) is compensated by rescaling \( \rho \) and \( \tau \) by the factor \( S \). That way, we retain all the previously obtained results for the particle abundances and the momentum spectra. However, now the system is more dilute and larger in size.
With our values of the thermodynamic parameters we have
\[ \sum_i P_i^0(T, \mu_i) = 80 \text{MeV/fm}^3, \]
which leads to \( S = 1.3 \) with \( r = 0.6 \text{fm}. \) Values of this
order have been typically obtained in other works. Thus, the excluded-volume corrections
can increase the size parameters at freeze-out by about 30\% and help to alleviate the
problem with the HBT radii. Hadrons have sizes!
(Anna Baran, to be published) Idea: fix azimuthal asymmetry of shape/flow with the data on pions, kaons, ... and then make predictions for other particles. solid (dashed): with (without) resonance decays. (data from PHENIX @ 200 GeV)
$v_2$ for strange particles

\begin{itemize}
  \item $\Lambda + \bar{\Lambda}$
  \item $K^0_s$
\end{itemize}

(data from STAR)

W. Broniowski, BNL’03
Summary

1. Works for abundances, $p_\perp$-spectra, including strange particles and resonances
2. Lower $T_{\text{kin}}$ would lead to much less resonances!
3. Resonances are an important source of correlations
4. Shape of the $\pi\pi$ “spectral line” - new thermometer, derivative of phase shifts must be used, full model gives similar results at 165 MeV to the naive calculation at 110 MeV (cooling via decays)
5. Not possible to place the $\rho$ peak at the experimental value. Medium effects? (Brown-Rho-Shuryak)
6. By summing up the resonance and non-resonance contributions we obtain the pion balance function with the shape similar to the data
7. $R_{\text{out}}/R_{\text{side}} \sim 1$
8. $v_2$ similar to hydro

Soft physics ($p_\perp < 1.5 - 2$) GeV is well described by the thermal approach with the single-freezeout approximation and resonance decays
